

Mobile Applications Project

Innovations:

- Added audience ratings by accessing the “vote_average” field that was already being returned by the trending and search APIs. Used toFixed(1) to take the returned number from 3 decimal places down to 1 for clarity.
- Added functionality to sort results based on their audience rating by using Javascript’s built in “sort()” array method, with a comparison function to sort the array in descending order.
- Adapted CSS flexbox layout properties to help make better use of open space on all pages of the application, displaying movie or cast details to the right of their image/poster, reducing unnecessary scrolling.
- Added a ‘back’ navigation button to all pages bar home using ion-buttons with an arrow-back icon, giving users an additional navigation option and making navigation flow more smoothly.
- Took the TMDB logo from the TMDB site and added it to the toolbar in all pages to give a cleaner and more professional look to the application.
- Added functionality to display the release dates of movies on their movie cards, which like the ‘vote_average’ was being returned anyways so no additional cost involved.
- Used the ion-searchbar component instead of ion-input on the search bar to get a built in magnifying glass icon and improved styling, giving a more polished appearance to the app.
- Chose Ionic Storage to implement the persistent storage requirement, set up async/await methods in DataService to ensure the application waits until what was in storage was fetched.

- Added a dark/light mode toggle, had previously defaulted to the user's OS dark/light mode setting. Added methods to DataService to handle functionality and uses localStorage to remember the user's selection after the app is closed.
